The LiquidChess Integration Protocol: Architectural Blueprint for Real-Time Persona Synthesis in Low-Latency Environments

1. Executive Summary

The convergence of large language models (LLMs) with real-time computer vision has opened new frontiers in automated game commentary. The 'LiquidChess' project—a proposed real-time chess commentary bot adopting the persona of an Aristocratic Vampire—presents a rigorous engineering challenge: synthesizing objective game state data (Stockfish 17) with subjective visual aesthetics (Vision-Language Models) and stylized narrative generation (LLMs) within a strict latency budget of under 1.5 seconds and a recurring operational cost of under $20 per month. This report provides a comprehensive technical audit of the requisite infrastructure, examining the integration of the Vision Layer, the reverse-engineering of undocumented data streams, and the prompt engineering methodologies required to maintain high-fidelity persona immersion without latency drift.

The analysis indicates that a monolithic approach using commercial APIs (e.g., OpenAI, Anthropic) is financially and computationally unfeasible for this specific use case. Instead, a distributed, hybrid-cloud architecture utilizing edge-optimized inference is required. The audit identifies **Groq's LPU-accelerated Llama 3** endpoints as the primary engine for textual synthesis due to their superior time-to-first-token (TTFT) metrics, while **Cloudflare Workers AI (Llama 3.2 11B Vision)** and **SiliconFlow (Pixtral 12B)** serve as the visual cortex, triggered asynchronously to preserve the real-time feedback loop.

Furthermore, the report uncovers critical data acquisition pathways via the undocumented callback/live/game endpoint of Chess.com, bypassing the latency inherent in the public REST API. By implementing custom Time Control Notation (TCN) decoding and utilizing "Context Anchoring" in prompt design, the system can sustain the "Count Lucian" persona—a weary, sophisticated observer—throughout prolonged blitz games without succumbing to the generic "helpful assistant" drift common in long-context interactions. The following sections detail the architectural decisions, validated by performance benchmarks and pricing models of the current generative AI landscape.

2. Vision Layer Architecture: Model Selection and Latency Engineering

The Vision Layer acts as the aesthetic sensor for the LiquidChess bot. Unlike traditional chess engines that perceive the game as a matrix of coordinates and material values (e.g., "e4", "+0.5 cp"), the LiquidChess mandate requires the perception of "Visual Vibe." The bot must "see" the board not just as data, but as a visual composition—detecting claustrophobic pawn structures, exposed diagonals that look "wounded," or jagged piece placements that suggest chaos. This requires a Vision-Language Model (VLM) capable of ingesting a board screenshot and outputting a stylistic description within strict latency bounds.

2.1. The VLM Landscape: Pixtral 12B vs. Llama 3.2 11B Vision

The constraints of the project (zero-to-low cost, high speed) narrow the field of candidate models significantly. The audit focuses on two primary open-weight contenders: **Pixtral 12B** (Mistral AI) and **Llama 3.2 11B Vision** (Meta), both of which are accessible via free-tier API providers.

2.1.1. Pixtral 12B: Architectural Capabilities

Pixtral 12B represents a significant evolution in multimodal architecture. Unlike previous models that simply patched a vision encoder onto a text decoder, Pixtral integrates a natively trained 400M parameter vision encoder with a 12B multimodal decoder based on Mistral Nemo.[1]

Variable Resolution Handling: A critical advantage of Pixtral for chess analysis is its implementation of **2D Rotary Positional Embeddings (RoPE-2D)**.[3] This allows the model to process images at their native resolution and aspect ratio without aggressive downscaling or padding. In the context of a chessboard, where the distinction between a pawn and a bishop can depend on subtle visual cues in a dense 64-square grid, standard fixed-resolution encoders often blur these details. Pixtral's ability to ingest high-resolution data ensures that the "visual vibe" assessment is based on accurate piece identification rather than hallucinated shapes.

Performance Benchmarks: Empirical data suggests Pixtral outperforms models in its weight class, including Qwen2-VL 7B and Llama 3.2 11B, on multimodal reasoning benchmarks like MMMU (52.5%) and MathVista (58.0%).[3] While "reasoning" is secondary to "aesthetic description" for this project, the model's grasp of spatial relationships is vital for describing piece clusters accurately.

Deployment Constraints: Despite its architectural superiority, Pixtral 12B's deployment on free-tier hardware presents latency challenges. Being a 12B parameter model, it requires substantial VRAM. On serverless platforms like SiliconFlow, cold starts and shared queue prioritization can lead to inference times exceeding 2-3 seconds, which violates the 1.5s real-time mandate.[3]

2.1.2. Llama 3.2 11B Vision: Edge Optimization

Meta's Llama 3.2 11B Vision is designed specifically for efficiency and edge deployment. It utilizes an adapter-based architecture to bridge a pre-trained image encoder with the Llama 3.1 text model.[6]

Throughput and Latency: The primary advantage of Llama 3.2 11B in this pipeline is its deep integration with high-performance inference providers like **Groq** and **Cloudflare Workers AI**.

- **Cloudflare:** Leverages a global edge network, running inference on serverless GPUs physically closer to the user.[7]
- **Groq:** Utilizes the Language Processing Unit (LPU), a hardware architecture designed to eliminate the memory bandwidth bottlenecks of traditional GPUs. This results in significantly faster sequential token generation.[8]

Trade-offs: While Llama 3.2 11B may lack the native multi-image handling and arbitrary resolution flexibility of Pixtral, its speed advantage is decisive. For a chess bot that must react to a blitz move (often played in <2 seconds), the difference between 500ms (Groq) and 2000ms (SiliconFlow) is the difference between "real-time commentary" and "laggy retro-analysis."

2.2. Hardware Infrastructure and Latency Audit

To meet the sub-1.5s latency target while remaining under the $20 budget, we must exploit the specific "Free Tier" mechanics of various providers. The following analysis breaks down the latency profiles and quotas.

2.2.1. SiliconFlow (Pixtral 12B Host)

SiliconFlow aggregates various open-source models, offering a compelling free tier for developers.

- **Rate Limits:** The platform enforces limits based on Requests Per Minute (RPM) and Tokens Per Minute (TPM). For free usage, these are typically fixed values (e.g., 1000 RPM for chat models, but undefined/lower for multimodal).[10]
- **Latency Variability:** As a "free forever" offering for specific models, SiliconFlow's infrastructure is subject to high contention. Without a paid SLA, inference requests are often queued. A queued request for Pixtral 12B can experience a "Time to First Token" (TTFT) of 1-3 seconds, followed by generation time.
- **Verdict:** While Pixtral 12B is a superior model for visual nuances, SiliconFlow's free tier latency is too unpredictable for the primary real-time loop. It is recommended only as a secondary analyzer for post-game summaries where latency is irrelevant.

2.2.2. Cloudflare Workers AI (Llama 3.2 Vision Host)

Cloudflare's model pricing and limits are unique, utilizing a unit called "Neurons" to abstract GPU compute time.

- **Free Allocation:** Users receive **10,000 Neurons per day** across all models.[11]
- **Cost Analysis for Vision:** The Llama 3.2 11B Vision model costs approximately **4,410 Neurons per 1 Million input tokens**.[11]
  - *Image Tokenization:* A standard high-resolution image (e.g., 1024x1024) is tokenized by the vision encoder. Estimates place a single image input at roughly 1,500 to 2,500 tokens depending on patch size.
  - *Cost per Request:* Assuming 2,000 tokens per image request:

$$2,000 \text{ tokens} \times \frac{4,410 \text{ Neurons}}{1,000,000 \text{ tokens}} \approx 8.82 \text{ Neurons}$$

  - *Daily Capacity:*

$$\frac{10,000 \text{ Neurons/day}}{8.82 \text{ Neurons/req}} \approx 1,133 \text{ images/day}$$

- **Latency Profile:** Cloudflare aims for <1s inference for edge models. However, "cold starts" (loading the model into GPU memory) can add 2-4 seconds if the endpoint hasn't been hit recently.[12] Once warm, latency stabilizes around 800ms-1.2s.
- **Verdict:** Viable for intermittent visual checks. The capacity of ~1,100 requests covers roughly 25 full chess games (assuming 40 moves) or considerably more if visual checks are throttled (e.g., only checking every 5 moves).

2.2.3. Groq (Llama 3.2 Vision Host)

Groq is the gold standard for latency in this audit.

- **Speed:** Groq's LPUs deliver inference speeds often exceeding 100 tokens per second for text, and sub-500ms processing for vision inputs.[13]
- **Free Tier Limits:** Groq currently offers a "Free Beta" tier. Limits are dynamic but typically set around **30 requests per minute (RPM)** or **14,400 requests per day** for specific models like Llama 3.2.[15]
- **Reliability:** The primary risk with Groq's free tier is aggressive rate limiting (HTTP 429) during peak global usage.
- **Verdict: Primary Execution Engine.** The speed allows the pipeline to "buy back" time. If Vision takes 400ms and Text generation takes 200ms, the system has ample overhead for network transmission and Python logic within the 1.5s window.

2.3. Hybrid Pipeline Recommendation

To satisfy the requirements, the LiquidChess architecture must be hybrid:

1. **Primary Inference (Text): Groq** (Llama 3 70B/8B) for generating the commentary text. The speed is non-negotiable for real-time interaction.
2. **Primary Inference (Vision): Groq** (Llama 3.2 11B Vision) for visual snapshots.

3. **Fallback Inference: Cloudflare Workers AI**. The Python controller must implement a try-catch block. If Groq returns a 429 (Rate Limit) or 503 (Service Unavailable), the request immediately routes to Cloudflare. This redundancy ensures the bot never "hangs" during a live broadcast.

Table 1: Comparative Latency and Cost Audit

Provider	Model	Typical Latency (Cold/Warm)	Free Tier Capacity	Suitability
SiliconFlow	Pixtral 12B	3.0s / 1.5s	Variable (Queue dependent)	**Low** (Too slow/unstable)
Cloudflare	Llama 3.2 11B	3.0s / 0.9s	~1,100 Images/Day (10k Neurons)	**Medium** (Excellent backup)
Groq	Llama 3.2 11B	0.8s / 0.4s	~30 RPM (Subject to load)	**High** (Critical for real-time)

3. Data Acquisition Pipeline: The "Callback" Protocol

The standard Chess.com Public API (PubAPI) is designed for archival data and has a caching delay of up to 12 hours, making it functionally useless for real-time commentary.[17] To achieve real-time synchronization, the LiquidChess bot must tap into the internal data streams used by the Chess.com browser client.

3.1. The callback/live/game Endpoint

Deep analysis of client-server traffic reveals a specific endpoint used for state synchronization: https://www.chess.com/callback/live/game/{game_id}. Unlike the CometD WebSocket stream, which requires complex handshake authentication, session cookies, and heartbeat maintenance [18], the callback endpoint acts as a stateless REST resource that returns the current game snapshot in JSON format.[20]

- **Latency:** The endpoint reflects the state immediately after the server processes a move. Network latency is standard HTTP (typically 50-150ms).
- **Payload:** The JSON response contains player clocks, material count, and crucially, a moveList field.

- **Security/Access:** This endpoint can generally be accessed without a logged-in session cookie, provided a valid User-Agent header is supplied to avoid immediate firewall rejection.[17]

3.2. Decoding Time Control Notation (TCN)

The moveList returned by the callback endpoint is not in standard PGN or UCI format. It uses a proprietary compression scheme known as **TCN (Time Control Notation)** to minimize bandwidth overhead.[20]

The TCN Algorithm:

TCN encodes each chess move into exactly two characters. The string length is therefore always $2 \times \text{PlyCount}$.

1. **Character Map:** The decoding relies on a specific 78-character lookup string: "abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ0123456789!?{~}(^)[_]@#$,./&-*++="
2. **Decoding Logic:**
   - Each move consists of two characters, C_1 and C_2.
   - The index of C_1 in the lookup string roughly corresponds to the "from" square.
   - The index of C_2 corresponds to the "to" square.
   - The algorithm handles "promotion" and "drop" quirks by mapping indices > 63 to special move types.[23]

Python Implementation Strategy: The chess-tcn library [24] is the specific Python package required to handle this decoding. It ports the JavaScript logic found in the Chess.com frontend.

- *Requirement:* pip install chess-tcn
- *Integration:* The raw string from callback is passed to chess_tcn.decode(), which returns a list of dictionaries (e.g., {'from': 'e2', 'to': 'e4'}). These must then be fed into a python-chess board instance to maintain the game state.

3.3. Polling Strategy and Rate Limiting

While WebSockets offer "push" updates, the engineering overhead for maintaining a stable CometD client in Python is high compared to polling.[27] For a single active game, an adaptive polling strategy is sufficient and falls within acceptable usage limits.

- **Adaptive Polling:**
  - *If User's Turn:* Poll frequency = 0.5s (High urgency).
  - *If Opponent's Turn:* Poll frequency = 2.0s (Low urgency).
  - *User-Agent:* Must be descriptive (e.g., LiquidChess-Bot/1.0 (contact: email)) to

comply with Chess.com's identification requests.[17]

- **Session Management:** Using requests.Session() is mandatory to reuse TCP connections (Keep-Alive), saving the ~100ms SSL handshake overhead on every poll.

4. The Cognitive Engine: Blending Stockfish and Heuristics

The "Aristocratic Vampire" persona requires inputs that go beyond simple win/loss probabilities. Count Lucian does not care about "centipawn loss"; he cares about "suffocation," "dominance," and "chaos." We must bridge the gap between engine metrics and aesthetic descriptors.

4.1. Stockfish 17 Integration

We utilize the python-chess library to interface with a local Stockfish 17 binary via the UCI protocol.[28]

- **Constraint:** To maintain the 1.5s latency budget, the engine analysis must be strictly capped.
- **Configuration:** limit = chess.engine.Limit(time=0.1) (100ms).
- **Output:** We extract the Score (cp) and the Principal Variation (PV).

4.2. Heuristic Extraction for "Vibe"

To fuel the persona, we calculate specific geometric features using python-chess board bitboards. These heuristics serve as "sensory inputs" for the Vampire [30]:

1. **Mobility (The Suffocation Index):**
   - *Logic:* Calculate the total number of legal moves available to the opponent.
   - *Code Concept:* len(list(board.legal_moves))
   - *Persona Mapping:*
     - High Mobility (>40 moves): "The prey runs wild... chaotic vitality."
     - Low Mobility (<15 moves): "Do you feel the walls closing in? The air is growing stale."
2. **Center Control (The Dominance Index):**
   - *Logic:* Count the number of friendly pieces attacking the squares e4, d4, e5, d5.
   - *Code Concept:* Using board.attackers(color, square) for the central squares.[32]
   - *Persona Mapping:* High control is interpreted as "Aristocratic Authority."
3. **Tension (The Bloodlust Index):**
   - *Logic:* Count the number of pieces currently under attack.
   - *Code Concept:* Iterate squares and check board.is_attacked_by.
   - *Persona Mapping:* High tension is "The scent of spilled blood is imminent."

4.3. The Visual "Vibe" Check

Generating a visual description via the VLM (Llama 3.2 Vision) every move is wasteful and potentially slow. The "Liquid" architecture triggers a visual check only on **Significant Events**:

- Evaluation swings > 200cp (Blunder/Brilliance).
- Piece capture.
- Every 10th move (to reassess the structure).

Visual Prompt:

> "Analyze the geometry of this chess position. Ignore the rules. Describe the visual texture: is it cramped and suffocating, or open and barren? Do the pieces look like a disorganized mob or a disciplined phalanx? Answer in 10 vivid words."

5. Persona Injection: The Aristocratic Vampire

The success of the bot lies in "Persona Injection." LLMs naturally drift toward being helpful assistants. To maintain the "Count Lucian" persona, we must use **Context Anchoring** and specific prompt structures.

5.1. Persona Archetype Analysis

Drawing from the literary traditions of Polidori's Lord Ruthven and Stoker's Dracula, the aristocratic vampire archetype is defined by **ennui**, **superiority**, and **predatory sophistication**.[33]

- **Ennui:** He has seen millions of games. Most moves are boring. He craves novelty.
- **Superiority:** He views humans as "mortals" or "cattle." Mistakes are "vulgar."
- **Predatory:** He uses language of consumption ("delicious," "draining," "succulent").

5.2. System Prompt Engineering

To prevent hallucination (inventing moves) and drift, we use a structured system prompt that separates the **Role** from the **Data**.

System Prompt Template:

You are Count Lucian, a 600-year-old aristocratic vampire. You view chess not as a game, but as a simulation of court intrigue and warfare. You are weary of mediocrity but exhilarated by cruelty.

1. NEVER offer helpful advice. You are an observer, not a coach.
2. NEVER calculate lines or predict future moves. Focus only on the present geometry.
3. Use archaic, sensory language (blood, shadows, velvet, suffocating, hunting).
4. Keep responses under 2 sentences.

- Evaluation: {eval_score} (Positive = White advantage)
- Visual Vibe: {vlm_description}
- Tactical State: {tension_index} pieces hanging.

- Mobility: {mobility_index} moves available.

Comment on the last move: {last_move_san}. If the move was a blunder, mock the player's short lifespan. If it was brilliant, praise the "beautiful cruelty."

5.3. Drift Prevention: Ephemeral Context

Research on prompt engineering suggests that long conversation histories dilute the system prompt.[35] For LiquidChess, we implement **Stateless Prompting**:

- We do *not* send the entire chat history to Groq every turn.
- We send only the **System Prompt** + **Last 2 Moves** + **Current State**.
- This ensures every response is generated with the "fresh" intensity of the persona definition, preventing the "helpful assistant" mode from creeping in over a 50-move game.

6. Implementation Plan and Specifics

6.1. Python Library Requirements

The following specific versions and libraries are required to build the stack:

- python-chess: Core board logic and UCI engine management.[37]
- chess-tcn: Essential for decoding the Chess.com callback stream.[24]
- requests: For HTTP polling (use requests.Session).
- groq: Official client for Llama 3 text generation.
- cairosvg: To convert python-chess SVG board representations into PNGs for the Vision API (requires libcairo2 system dependency).

6.2. Python Code Snippet: The TCN Decoder & Poller

Python

```python
import requests
import chess
import chess.pgn
# Note: chess-tcn library must be installed via pip
from chess_tcn import decode_tcn

def get_live_state(game_id_numeric):
    url = f"https://www.chess.com/callback/live/game/{game_id_numeric}"
    headers = {'User-Agent': 'LiquidChess-Vampire/1.0'}
```

```
with requests.Session() as session:
    response = session.get(url, headers=headers, timeout=1.5)
    if response.status_code == 200:
        data = response.json()
        tcn_string = data.get('moveList', '')
        # Decodes TCN string into a list of move dicts {'from': 'e2', 'to': 'e4'}
        moves = decode_tcn(tcn_string)
        return moves
return None
```

6.3. Budget Audit

- **VPS Hosting:** DigitalOcean Droplet (1 vCPU, 1GB RAM) - **$4.00/mo**.
- **Groq API:** Free Beta Tier (sufficient for text generation) - **$0.00**.
- **Cloudflare Workers AI:** Free Tier (10k Neurons/day). Used as fallback/secondary vision - **$0.00**.
- **Chess.com API:** Public/Callback - **$0.00**.
- **Total Monthly Cost: ~$4.00**.

7. Conclusion

The "LiquidChess" project is technically viable within the aggressive constraints set forth. The key to success lies in the **hybridization of data sources**: utilizing the undocumented Chess.com callback endpoint for real-time speed, Stockfish for objective truth, and Groq/Cloudflare for the aesthetic synthesis. By treating the Vision Layer not as a primary state tracker but as a "Vibe Sensor" triggered on significant events, the system respects the 1.5s latency budget while delivering the rich, atmospheric commentary demanded by the "Aristocratic Vampire" persona. The proposed architecture moves beyond simple chatbots, creating a reactive, multimodal agent that perceives the game with the same sophisticated weariness as its fictional counterpart.

---

1. System Architecture Overview

The LiquidChess system operates as a **Man-in-the-Middle (MITM) Observer**. It does not play the game; it watches, judges, and comments. The architecture is designed to minimize the "Loop Latency"—the time between a move occurring on the board and the commentary appearing in the chat.

1.1 High-Level Data Flow

1. **Ingest:** The Python Controller polls the Chess.com callback endpoint (every ~0.5s - 2s).
2. **Decode:** The Controller detects a change in the moveList string, decodes the TCN (Time Control Notation) into UCI moves, and updates the internal python-chess.Board state.
3. **Analyze (Parallel):**
    - **Path A (Engine):** Stockfish 17 evaluates the position (capped at 100ms).
    - **Path B (Heuristics):** Python scripts calculate mobility and tension indices (<10ms).
    - **Path C (Vision - Conditional):** If the move is significant, the board is rendered to an image and sent to Llama 3.2 Vision (Groq/Cloudflare) for aesthetic analysis.
4. **Synthesize:** All inputs (Eval, Vibe, Move) are formatted into a prompt and sent to Groq (Llama 3 70B) for persona generation.
5. **Broadcast:** The resulting commentary is displayed or spoken.

1.2 Latency Budget Breakdown (Target: <1.5s)

Component	Action	Est. Time	Technology
Network	Poll Chess.com	150ms	requests.Session (Keep-Alive)

Compute	Decode TCN & Update Board	20ms	chess-tcn, python-chess
Analysis	Stockfish Eval	100ms	Hard limit time=0.1
Vision	Llama 3.2 Vision Inference	400ms	Groq LPU (Conditional)
Synthesis	Llama 3 Text Generation	300ms	Groq LPU (Llama 3 70B)
Overhead	Network RTT & Parsing	200ms	Python logic
Total	**End-to-End Latency**	**~1.17s**	**Within 1.5s Target**

Note: If the Vision Layer (400ms) runs every turn, we are close to the limit. Therefore, the architecture recommends asynchronous vision processing, where the "Vibe" is updated every few seconds rather than blocking every move commentary.

---

2. Vision Layer Implementation

The Vision Layer differentiates LiquidChess from standard bots. It provides the "subjective" input required for the Vampire persona to make comments like "How droll, the pieces are clustered like frightened sheep," rather than just "White is +2."

2.1 Model Audit: Pixtral 12B vs. Llama 3.2 11B Vision

We evaluated two leading open-weight multimodal models suitable for free-tier use.

Pixtral 12B (Mistral AI): Pixtral uses a novel **2D Rotary Positional Embedding (RoPE-2D)** in its vision encoder. This is highly relevant for chess because it allows the model to process images at native resolutions without warping the aspect ratio.[3] Standard encoders often resize images to fixed squares (e.g., 224x224 or 336x336), which can blur the distinction between similar-looking pieces (e.g., Queen vs. Bishop) on a crowded board. Pixtral's variable resolution handling ensures high fidelity for the chessboard grid.[2] However, Pixtral is computationally heavy. On **SiliconFlow's** free tier, which operates on shared resources,

latency is unpredictable and often exceeds the 1.5s budget due to queuing.[10]

Llama 3.2 11B Vision (Meta): This model is optimized for "edge" scenarios. It uses an adapter architecture to connect a vision encoder to the Llama 3 language model. While it may lack the granular resolution handling of Pixtral, its integration into **Groq's** LPU infrastructure makes it the speed champion. Groq's hardware is designed for sequential processing, delivering inference times that are consistently sub-second.[9]

Conclusion: For a real-time bot, **Llama 3.2 11B Vision** hosted on Groq is the only choice that fits the latency budget. Pixtral 12B on SiliconFlow is relegated to post-game analysis functionality.

2.2 The Case for Groq LPU vs. Cloudflare Neurons

Cloudflare Workers AI:

Cloudflare uses a "Neuron" pricing model.

- **Free Limit:** 10,000 Neurons/day.
- **Cost Efficiency:** Llama 3.2 11B Vision costs ~4,410 Neurons per 1 Million input tokens.[11]
- **Capacity:** A single board image is ~2,000 tokens. This equates to roughly ~9 Neurons per image. The daily limit allows for ~1,100 images.[11]
- **Latency:** Cloudflare runs on edge GPUs. Cold starts are a significant risk (2-3s latency), which disrupts real-time flow.[12]

Groq Cloud:

Groq uses a Rate Limit model (RPM/TPM).

- **Free Beta:** Allows for high-speed access with limits (e.g., 30 Requests Per Minute).
- **Latency:** Consistently <500ms for vision tasks due to LPU architecture.
- **Strategy:** 30 RPM is sufficient for a chess game (moves rarely occur faster than every 2 seconds consistently). Groq allows for real-time "stream of consciousness" commentary.

2.3 Cost & Capacity Analysis

The project requires a budget of <$20.

Resource	Service	Tier	Cost	Note
Vision API	Groq / Cloudflare	Free	$0.00	Use Groq primarily; fallback to Cloudflare if rate-limited.

Text API	Groq	Free	$0.00	Llama 3 70B is free in Beta (limited RPM).
Compute	VPS (Hetzner)	CX22	~$5.00	2 vCPU, 4GB RAM is plenty for Python + Stockfish.
Total			**~$5.00**	**Well under $20 budget.**

---

3. Real-Time Data Engineering

The biggest hurdle for chess bots is getting data *fast*.

3.1 The callback/live/game Endpoint

Most developers attempt to use the Chess.com PubAPI (api.chess.com/pub/player...). This is a mistake. The PubAPI uses aggressive caching (CDN), meaning data can be 10 minutes to 12 hours old.[17]

Deep research into the Chess.com web client identifies the internal endpoint used for game state synchronization:

URL: https://www.chess.com/callback/live/game/{game_id}

- **Method:** GET
- **Response:** JSON containing moveList (string), clocks (array), and isGameOver (boolean).
- **Access:** Requires a generic User-Agent. Does not strictly require a session cookie for public games, making it ideal for a bot.[20]

3.2 TCN Decoding Algorithm

The moveList returned by this endpoint is encoded in **TCN (Time Control Notation)**. This is a proprietary compression algorithm where every move is represented by exactly **two characters**.

The TCN Algorithm Mechanics:

1. **Lookup String:** A specific 78-character string acts as the cipher key: "abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ0123456789!?{~}(^)[_]@#$,./&-*++="

2. **Decoding Pairs:** The bot reads the string in 2-character chunks.
    - **Char 1 (From Square):** The index of this character in the lookup string roughly maps to the source square (0-63).
    - **Char 2 (To Square):** The index maps to the destination square.
    - *Special Cases:* Indices > 63 map to promotion types (Queen, Rook, etc.) or "drops" in variants like Crazyhouse.[23]

Python Implementation: We utilize the chess-tcn library available on PyPI.[24]

Python

```python
from chess_tcn import decode_tcn
import chess

# TCN string from API response
tcn_str = "mC0Kgv7T"
# Decoding
moves = decode_tcn(tcn_str)
# Result: [{'from': 'e2', 'to': 'e4'}, {'from': 'e7', 'to': 'e5'},...]

# Updating Python-Chess Board
board = chess.Board()
for move in moves:
    # Convert dict to chess.Move
    uci_move = chess.Move.from_uci(f"{move['from']}{move['to']}")
    board.push(uci_move)
```

3.3 Polling vs. WebSocket Strategy

While Chess.com uses a CometD (Long Polling/WebSocket) protocol for its frontend [18], reverse-engineering the handshake authentication is fragile and violates the complexity constraint.

The "Aggressive Polling" Compromise:

Instead of maintaining a socket, the bot performs "micro-polling" on the callback endpoint.

- **Technique:** Use requests.Session to maintain a persistent TCP connection (Keep-Alive).
- **Frequency:** Poll every 0.5s when it is the monitored player's turn. Poll every 2.0s when it is the opponent's turn.
- **Impact:** This adds ~150ms of latency (Network RTT) compared to a WebSocket, but

drastically simplifies the codebase and robustness.[27]

---

4. Cognitive Architecture

The "Brain" of LiquidChess consists of two hemispheres: the objective calculator (Stockfish) and the subjective artist (Heuristics).

4.1 Stockfish 17 Integration (UCI)

We interface with Stockfish using the python-chess UCI manager.

- **Latency Cap:** result = engine.play(board, chess.engine.Limit(time=0.1))
- **Data Extraction:** We extract the score (centipawns) and pv (principal variation/best line).
- **Role:** This prevents the Vampire from hallucinating. If Stockfish says "Mate in 3," the Vampire knows the end is near.

4.2 Python-Chess Heuristics (Defining the "Vibe")

To give the Vampire "senses," we calculate geometric features directly in Python.[30]

1. The Suffocation Index (Mobility):

Does the opponent have space, or are they crushed?

Python

```python
def get_mobility_score(board, color):
    return len(list(board.generate_legal_moves(from_mask=board.occupied_co[color])))
```

- *Interpretation:* If mobility < 10, the Vampire comments on the "delicious claustrophobia."

2. The Dominance Index (Center Control):

Who owns the center?

Python

```python
def get_center_control(board, color):
```

```
    center_squares =
    control_score = 0
    for sq in center_squares:
        if board.is_attacked_by(color, sq):
            control_score += 1
    return control_score
```

- *Interpretation:* High control = "Imperial domination."

---

5. Persona Synthesis (The Vampire Layer)

The final layer is the "Persona Injection." We use Llama 3 70B (via Groq) to synthesize the data into the voice of **Count Lucian**.

5.1 Archetypal Analysis & Voice

Literary analysis of the aristocratic vampire archetype (Polidori's *The Vampyre*, Stoker's *Dracula*) reveals key traits suitable for prompt engineering [33]:

1. **Old Money Ennui:** A weariness with the repetitive nature of life (and chess).
2. **Predatory Sophistication:** Viewing others as "cattle" or "vessels."
3. **Aestheticism:** Valuing beauty and "style" over utility.

5.2 System Prompt Design

To blend the "Vibe" (Vision/Heuristics) with the "Math" (Stockfish), the prompt must explicitly map data points to narrative metaphors.

The "Count Lucian" System Prompt:

You are Count Lucian, a 600-year-old aristocratic vampire observing a chess match.

You find modern life vulgar and hasty. You are deeply bored, but easily captivated by "cruelty" on the board.

- Evaluation (Math): The objective truth of the position.
  - If +Win: "The white neck is exposed."
  - If -Win: "Black shadows consume the light."
  - If Draw: "An eternal, stagnant purgatory."
- Visual Vibe (Aesthetics): The texture of the board.
  - Cramped: "Suffocating... delicious."
  - Open: "Barren and bright. Disgusting."

1. DO NOT act like a helper. You are a critic.
2. DO NOT calculate variations. You are above such manual labor.
3. Keep commentary under 20 words.

5.3 Context Anchoring & Drift Prevention

In long games (50+ moves), LLMs drift and become generic "helpful assistants." To prevent this, we use **Stateless Prompting** (or Ephemeral Context).[35]

- **The Pattern:** We do *not* maintain a chat history in the prompt.
- **The Injection:** Every API call to Groq contains the *full* System Prompt + only the *Last Move*.
- **Why:** This forces the model to "re-inhabit" the persona from scratch every 2 seconds, ensuring maximum adherence to the character constraints without dilution from previous conversational turns.

---

6. Budget & Stack Audit

6.1 Specific Libraries

The Python environment requires:

1. python-chess (v1.10+): Board logic.
2. chess-tcn (v1.0.0): TCN decoding.[26]
3. groq: API client.
4. cairosvg: For rendering board states to PNG for Vision calls.
5. requests: For HTTP polling.

6.2 Cost Breakdown

- **Cloudflare Workers AI:** 10,000 Neurons/day (Free). Used for occasional "Vibe Checks" (Vision). Cost: **$0**.[11]
- **Groq API:** Free Beta Tier. Used for high-speed Text & Vision. Cost: **$0**.
- **VPS:** Small Linux instance. Cost: **$5/mo**.
- **Total: $5/mo**.

This architecture successfully delivers a sophisticated, real-time, vision-enhanced chess bot within the strict constraints of the user's request.
